# Package: statsExpressions (via r-universe)

June 17, 2024

Type Package

Title Tidy Dataframes and Expressions with Statistical Details

Version 1.5.4.9000

Description Utilities for producing dataframes with rich details for the most common types of statistical approaches and tests: parametric, nonparametric, robust, and Bayesian t-test, one-way ANOVA, correlation analyses, contingency table analyses, and meta-analyses. The functions are pipe-friendly and provide a consistent syntax to work with tidy data. These dataframes additionally contain expressions with statistical details, and can be used in graphing packages. This package also forms the statistical processing backend for 'ggstatsplot'. References: Patil (2021) <doi:10.21105/joss.03236>.

add\_expression\_col Template for expressions with statistical details

### Description

Creates an expression from a data frame containing statistical details. Ideally, this data frame would come from having run tidy\_model\_parameters function on your model object.

This function is currently **not** stable and should not be used outside of this package context.

3 add\_expression\_col

#### Usage

```
add_expression_col(
  data,
  paired = FALSE,
  statistic.text = NULL,
  effsize.text = NULL,
  prior.type = NULL,
  n = NULL,
  n.text = ifelse(paired, list(quote(italic("n")["pairs"])),
    list(quote(italic("n")["obs"]))),
  digits = 2L,
  digits.df = 0L,
  digits.df.error = digits.df,
)
```

### **Arguments**

data

A data frame containing details from the statistical analysis and should contain some or all of the the following columns:

- statistic: the numeric value of a statistic.
- df.error: the numeric value of a parameter being modeled (often degrees of freedom for the test); irrelevant. if there are no degrees of freedom.
- df: relevant if the statistic in question has two degrees of freedom.
- *p.value*: the two-sided *p*-value associated with observed statistic.
- *method*: method describing the test carried out.
- effectsize: name of the effect size (if not present, same as method).
- estimate: estimated value of the effect size.
- conf.level: width for the confidence intervals.
- conf.low: lower bound for effect size estimate.
- conf.high: upper bound for effect size estimate.
- *bf10*: Bayes Factor value (if bayesian = TRUE).

paired

n.text

Logical that decides whether the experimental design is repeated measures/withinsubjects or between-subjects. The default is FALSE.

statistic.text A character that specifies the relevant test statistic. For example, for tests with t-statistic, statistic.text = "t".

effsize.text A character that specifies the relevant effect size.

prior.type The type of prior.

An integer specifying the sample size used for the test.

A character that specifies the design, which will determine what the n stands for. It defaults to quote(italic("n")["pairs"]) if paired = TRUE, and to quote(italic("n")["obs"]) if paired = FALSE. If you wish to customize this further, you will need to provide object of language type.

digits, digits.df, digits.df.error

Number of decimal places to display for the parameters (default: 0L).

Currently ignored.

4 bugs\_long

#### **Examples**

```
set.seed(123)
# creating a data frame with stats results
stats_df <- cbind.data.frame(</pre>
 statistic = 5.494,
      = 29.234
 p.value = 0.00001, estimate = -1.980,
 conf.level = 0.95,
 conf.low = -2.873,
 conf.high = -1.088,
 method
            = "Student's t-test"
)
# expression for *t*-statistic with Cohen's *d* as effect size
# note that the plotmath expressions need to be quoted
add_expression_col(
 data
                = stats_df,
 statistic.text = list(quote(italic("t"))),
 effsize.text = list(quote(italic("d"))),
                 = 32L,
                = list(quote(italic("n")["no.obs"])),
 n.text
 digits
                = 3L,
 digits.df
                = 3L
```

bugs\_long

Tidy version of the "Bugs" dataset.

### **Description**

Tidy version of the "Bugs" dataset.

#### Usage

bugs\_long

#### **Format**

A data frame with 372 rows and 6 variables

- subject. Dummy identity number for each participant.
- gender. Participant's gender (Female, Male).
- region. Region of the world the participant was from.
- education. Level of education.

centrality\_description 5

condition. Condition of the experiment the participant gave rating for (LDLF: low freight-eningness and low disgustingness; LFHD: low freighteningness and high disgustingness; HFHD: high freighteningness and low disgustingness; HFHD: high freighteningness and high disgustingness).

• desire. The desire to kill an arthropod was indicated on a scale from 0 to 10.

#### **Details**

This data set, "Bugs", provides the extent to which men and women want to kill arthropods that vary in freighteningness (low, high) and disgustingness (low, high). Each participant rates their attitudes towards all anthropods. Subset of the data reported by Ryan et al. (2013).

#### Source

https://www.sciencedirect.com/science/article/pii/S0747563213000277

#### **Examples**

```
dim(bugs_long)
head(bugs_long)
dplyr::glimpse(bugs_long)
```

centrality\_description

Data frame and expression for distribution properties

### Description

Parametric, non-parametric, robust, and Bayesian measures of centrality.

#### Usage

```
centrality_description(
  data,
  x,
  y,
  type = "parametric",
  conf.level = NULL,
  tr = 0.2,
  digits = 2L,
  ...
)
```

#### **Arguments**

data A data frame (or a tibble) from which variables specified are to be taken. Other data types (e.g., matrix,table, array, etc.) will **not** be accepted. Additionally, grouped data frames from {dplyr} should be ungrouped before they are entered as data. The grouping (or independent) variable in data. Х The response (or outcome or dependent) variable from data. У A character specifying the type of statistical approach: type • "parametric" • "nonparametric" • "robust" • "bayes" You can specify just the initial letter. conf.level Scalar between 0 and 1 (default: 95% confidence/credible intervals, 0.95). If NULL, no confidence intervals will be computed. Trim level for the mean when carrying out robust tests. In case of an error, tr try reducing the value of tr, which is by default set to 0.2. Lowering the value might help. Number of digits for rounding or significant figures. May also be "signif" to digits return significant figures or "scientific" to return scientific notation. Control the number of digits by adding the value as suffix, e.g. digits = "scientific4" to have scientific notation with 4 decimal places, or digits = "signif5" for 5 significant figures (see also signif()).

# Currently ignored.

This function describes a distribution for y variable for each level of the grouping variable in x by a set of indices (e.g., measures of centrality, dispersion, range, skewness, kurtosis, etc.). It additionally returns an expression containing a specified centrality measure. The function internally relies on datawizard::describe\_distribution() function.

#### **Centrality measures**

**Details** 

The table below provides summary about:

- statistical test carried out for inferential statistics
- type of effect size estimate and a measure of uncertainty for this estimate
- functions used internally to compute these details

Type	Measure	Function used
Parametric	mean	<pre>datawizard::describe_distribution()</pre>
Non-parametric	median	<pre>datawizard::describe_distribution()</pre>
Robust	trimmed mean	<pre>datawizard::describe_distribution()</pre>

Bayesian MAP datawizard::describe\_distribution()

### **Examples**

contingency\_table

Contingency table analyses

#### **Description**

Parametric and Bayesian one-way and two-way contingency table analyses.

### Usage

```
contingency_table(
  data,
  x,
  y = NULL,
  paired = FALSE,
  type = "parametric",
  counts = NULL,
  ratio = NULL,
  alternative = "two.sided",
  digits = 2L,
  conf.level = 0.95,
  sampling.plan = "indepMulti",
  fixed.margin = "rows",
  prior.concentration = 1,
  ...
)
```

#### **Arguments**

data A data frame (or a tibble) from which variables specified are to be taken. Other

data types (e.g., matrix,table, array, etc.) will **not** be accepted. Additionally, grouped data frames from {dplyr} should be ungrouped before they are entered

as data.

x The variable to use as the **rows** in the contingency table.

y The variable to use as the **columns** in the contingency table. Default is NULL.

If NULL, one-sample proportion test (a goodness of fit test) will be run for the  $\boldsymbol{x}$ 

variable.

paired Logical indicating whether data came from a within-subjects or repeated mea-

sures design study (Default: FALSE).

type A character specifying the type of statistical approach:

• "parametric"

• "nonparametric"

• "robust"

• "bayes"

You can specify just the initial letter.

counts The variable in data containing counts, or NULL if each row represents a single

observation.

ratio A vector of proportions: the expected proportions for the proportion test (should

sum to 1). Default is NULL, which means the null is equal theoretical proportions across the levels of the nominal variable. E.g., ratio = c(0.5, 0.5) for two

levels, ratio = c(0.25, 0.25, 0.25, 0.25) for four levels, etc.

alternative A character string specifying the alternative hypothesis; Controls the type of

CI returned: "two.sided" (default, two-sided CI), "greater" or "less" (one-sided CI). Partial matching is allowed (e.g., "g", "l", "two"...). See section

One-Sided CIs in the effectsize\_CIs vignette.

digits Number of digits for rounding or significant figures. May also be "signif" to

return significant figures or "scientific" to return scientific notation. Control the number of digits by adding the value as suffix, e.g. digits = "scientific4" to have scientific notation with 4 decimal places, or digits = "signif5" for 5

significant figures (see also signif()).

conf.level Scalar between 0 and 1 (default: 95% confidence/credible intervals, 0.95). If

NULL, no confidence intervals will be computed.

sampling.plan Character describing the sampling plan. Possible options are "indepMulti"

(independent multinomial; default), "poisson", "jointMulti" (joint multino-

mial), "hypergeom" (hypergeometric). For more, see ?BayesFactor::contingencyTableBF().

fixed.margin For the independent multinomial sampling plan, which margin is fixed ("rows"

or "cols"). Defaults to "rows".

prior.concentration

Specifies the prior concentration parameter, set to 1 by default. It indexes the expected deviation from the null hypothesis under the alternative, and corresponds

to Gunel and Dickey's (1974) "a" parameter.

.. Additional arguments (currently ignored).

#### Value

The returned tibble data frame can contain some or all of the following columns (the exact columns will depend on the statistical test):

- statistic: the numeric value of a statistic
- df: the numeric value of a parameter being modeled (often degrees of freedom for the test)
- df.error and df: relevant only if the statistic in question has two degrees of freedom (e.g. anova)
- p. value: the two-sided p-value associated with the observed statistic
- method: the name of the inferential statistical test
- estimate: estimated value of the effect size
- conf. low: lower bound for the effect size estimate
- conf. high: upper bound for the effect size estimate
- conf.level: width of the confidence interval
- conf. method: method used to compute confidence interval
- conf.distribution: statistical distribution for the effect
- effectsize: the name of the effect size
- n.obs: number of observations
- expression: pre-formatted expression containing statistical details

For examples, see data frame output vignette.

#### Contingency table analyses

The table below provides summary about:

- statistical test carried out for inferential statistics
- type of effect size estimate and a measure of uncertainty for this estimate
- functions used internally to compute these details

 )
}
```

12 corr\_test

corr\_test

Correlation analyses

#### **Description**

Parametric, non-parametric, robust, and Bayesian correlation test.

### Usage

```
corr_test(
   data,
   x,
   y,
   type = "parametric",
   digits = 2L,
   conf.level = 0.95,
   tr = 0.2,
   bf.prior = 0.707,
   ...
)
```

#### **Arguments**

data

A data frame (or a tibble) from which variables specified are to be taken. Other data types (e.g., matrix,table, array, etc.) will **not** be accepted. Additionally, grouped data frames from {dplyr} should be ungrouped before they are entered as data.

Х

The column in data containing the explanatory variable to be plotted on the x-axis.

У

The column in data containing the response (outcome) variable to be plotted on the y-axis.

type

A character specifying the type of statistical approach:

- "parametric"
- "nonparametric"
- "robust"
- "bayes"

You can specify just the initial letter.

digits

Number of digits for rounding or significant figures. May also be "signif" to return significant figures or "scientific" to return scientific notation. Control the number of digits by adding the value as suffix, e.g. digits = "scientific4" to have scientific notation with 4 decimal places, or digits = "signif5" for 5 significant figures (see also signif()).

conf.level

Scalar between 0 and 1 (default: 95% confidence/credible intervals, 0.95). If NULL, no confidence intervals will be computed.

corr\_test 13

tr Trim level for the mean when carrying out robust tests. In case of an error,

try reducing the value of tr, which is by default set to 0.2. Lowering the value

might help.

bf.prior A number between 0.5 and 2 (default 0.707), the prior width to use in calcu-

lating Bayes factors and posterior estimates. In addition to numeric arguments, several named values are also recognized: "medium", "wide", and "ultrawide", corresponding to r scale values of 1/2, sqrt(2)/2, and 1, respectively. In case of

an ANOVA, this value corresponds to scale for fixed effects.

. . . Additional arguments (currently ignored).

#### Value

The returned tibble data frame can contain some or all of the following columns (the exact columns will depend on the statistical test):

- statistic: the numeric value of a statistic
- df: the numeric value of a parameter being modeled (often degrees of freedom for the test)
- df.error and df: relevant only if the statistic in question has two degrees of freedom (e.g. anova)
- p. value: the two-sided p-value associated with the observed statistic
- method: the name of the inferential statistical test
- estimate: estimated value of the effect size
- conf.low: lower bound for the effect size estimate
- conf. high: upper bound for the effect size estimate
- conf. level: width of the confidence interval
- conf. method: method used to compute confidence interval
- conf.distribution: statistical distribution for the effect
- effectsize: the name of the effect size
- n.obs: number of observations
- expression: pre-formatted expression containing statistical details

For examples, see data frame output vignette.

### **Correlation analyses**

The table below provides summary about:

- statistical test carried out for inferential statistics
- type of effect size estimate and a measure of uncertainty for this estimate
- functions used internally to compute these details

#### Hypothesis testing and Effect size estimation

Type Test CI available? Function used

Parametric Pearson's correlation coefficient Yes correlation::correlation()

14 extract\_stats\_type

Non-parametric	Spearman's rank correlation coefficient	Yes	<pre>correlation::correlation()</pre>
Robust	Winsorized Pearson's correlation coefficient	Yes	<pre>correlation::correlation()</pre>
Bayesian	Bayesian Pearson's correlation coefficient	Yes	<pre>correlation::correlation()</pre>

#### **Examples**

### Description

Relevant mostly for {ggstatsplot} and {statsExpressions} packages, where different statistical approaches are supported via this argument: parametric, non-parametric, robust, and Bayesian. This switch function converts strings entered by users to a common pattern for convenience.

#### Usage

```
extract_stats_type(type)
stats_type_switch(type)
```

#### **Arguments**

type

A character specifying the type of statistical approach:

- "parametric"
- "nonparametric"
- "robust"
- "bayes"

You can specify just the initial letter.

iris\_long 15

#### **Examples**

```
extract_stats_type("p")
extract_stats_type("bf")
```

iris\_long

Edgar Anderson's Iris Data in long format.

### **Description**

Edgar Anderson's Iris Data in long format.

#### Usage

iris\_long

#### **Format**

A data frame with 600 rows and 5 variables

- id. Dummy identity number for each flower (150 flowers in total).
- Species. The species are Iris setosa, versicolor, and virginica.
- condition. Factor giving a detailed description of the attribute (Four levels: "Petal.Length", "Petal.Width", "Sepal.Length", "Sepal.Width").
- attribute. What attribute is being measured ("Sepal" or "Pepal").
- measure. What aspect of the attribute is being measured ("Length" or "Width").
- value. Value of the measurement.

#### **Details**

This famous (Fisher's or Anderson's) iris data set gives the measurements in centimeters of the variables sepal length and width and petal length and width, respectively, for 50 flowers from each of 3 species of iris. The species are Iris setosa, versicolor, and virginica.

This is a modified dataset from datasets package.

```
dim(iris_long)
head(iris_long)
dplyr::glimpse(iris_long)
```

```
long_to_wide_converter
```

Convert long/tidy data frame to wide format

#### **Description**

This conversion is helpful mostly for repeated measures design, where removing NAs by participant can be a bit tedious.

#### Usage

```
long_to_wide_converter(
  data,
  x,
  y,
  subject.id = NULL,
  paired = TRUE,
  spread = TRUE,
  ...
)
```

#### **Arguments**

data

A data frame (or a tibble) from which variables specified are to be taken. Other data types (e.g., matrix,table, array, etc.) will **not** be accepted. Additionally, grouped data frames from {dplyr} should be ungrouped before they are entered as data.

Х

The grouping (or independent) variable from data. In case of a repeated measures or within-subjects design, if subject.id argument is not available or not explicitly specified, the function assumes that the data has already been sorted by such an id by the user and creates an internal identifier. So if your data is **not** sorted, the results *can* be inaccurate when there are more than two levels in x and there are NAs present. The data is expected to be sorted by user in subject-1,subject-2, ..., pattern.

у

The response (or outcome or dependent) variable from data.

subject.id

Relevant in case of a repeated measures or within-subjects design (paired = TRUE, i.e.), it specifies the subject or repeated measures identifier. **Important**: Note that if this argument is NULL (which is the default), the function assumes that the data has already been sorted by such an id by the user and creates an internal identifier. So if your data is **not** sorted and you leave this argument unspecified, the results *can* be inaccurate when there are more than two levels in x and there are NAs present.

paired

Logical that decides whether the experimental design is repeated measures/withinsubjects or between-subjects. The default is FALSE.

spread

Logical that decides whether the data frame needs to be converted from long/tidy to wide (default: TRUE).

meta\_analysis 17

... Currently ignored.

#### Value

A data frame with NAs removed while respecting the between-or-within-subjects nature of the dataset.

#### **Examples**

```
# for reproducibility
library(statsExpressions)
set.seed(123)

# repeated measures design
long_to_wide_converter(
   bugs_long,
   condition,
   desire,
   subject.id = subject,
   paired = TRUE
)

# independent measures design
long_to_wide_converter(mtcars, cyl, wt, paired = FALSE)
```

meta\_analysis

Random-effects meta-analysis

### Description

Parametric, non-parametric, robust, and Bayesian random-effects meta-analysis.

#### Usage

```
meta_analysis(
   data,
   type = "parametric",
   random = "mixture",
   digits = 2L,
   conf.level = 0.95,
   ...
)
```

#### **Arguments**

data

A data frame. It **must** contain columns named estimate (effect sizes or outcomes) and std.error (corresponding standard errors). These two columns will be used:

18 meta\_analysis

• as yi and sei arguments in metafor::rma() (for **parametric** test) or metaplus::metaplus() (for **robust** test)

• as y and SE arguments in metaBMA::meta\_random() (for **Bayesian** test).

type A character specifying the type of statistical approach:

• "parametric"

• "nonparametric"

• "robust"

• "baves"

You can specify just the initial letter.

random The type of random effects distribution. One of "normal", "t-dist", "mixture",

for standard normal, t-distribution or mixture of normals respectively.

digits Number of digits for rounding or significant figures. May also be "signif" to

return significant figures or "scientific" to return scientific notation. Control the number of digits by adding the value as suffix, e.g. digits = "scientific4" to have scientific notation with 4 decimal places, or digits = "signif5" for 5

significant figures (see also signif()).

conf.level Scalar between 0 and 1 (default: 95% confidence/credible intervals, 0.95). If

NULL, no confidence intervals will be computed.

... Additional arguments passed to the respective meta-analysis function.

#### Value

The returned tibble data frame can contain some or all of the following columns (the exact columns will depend on the statistical test):

- statistic: the numeric value of a statistic
- df: the numeric value of a parameter being modeled (often degrees of freedom for the test)
- df.error and df: relevant only if the statistic in question has two degrees of freedom (e.g. anova)
- p. value: the two-sided p-value associated with the observed statistic
- method: the name of the inferential statistical test
- estimate: estimated value of the effect size
- conf. low: lower bound for the effect size estimate
- conf.high: upper bound for the effect size estimate
- conf.level: width of the confidence interval
- conf.method: method used to compute confidence interval
- conf. distribution: statistical distribution for the effect
- effectsize: the name of the effect size
- n. obs: number of observations
- expression: pre-formatted expression containing statistical details

For examples, see data frame output vignette.

meta\_analysis 19

#### Random-effects meta-analysis

The table below provides summary about:

- statistical test carried out for inferential statistics
- type of effect size estimate and a measure of uncertainty for this estimate
- functions used internally to compute these details

#### Hypothesis testing and Effect size estimation

Type	Test	CI available?	Function used
Parametric	Pearson's correlation coefficient	Yes	<pre>correlation::correlation()</pre>
Non-parametric	Spearman's rank correlation coefficient	Yes	<pre>correlation::correlation()</pre>
Robust	Winsorized Pearson's correlation coefficient	Yes	<pre>correlation::correlation()</pre>
Bayesian	Bayesian Pearson's correlation coefficient	Yes	<pre>correlation::correlation()</pre>

#### Note

**Important**: The function assumes that you have already downloaded the needed package ({metafor}, {metaplus}, or {metaBMA}) for meta-analysis. If they are not available, you will be asked to install them.

20 movies\_long

movies\_long

Movie information and user ratings from IMDB.com (long format).

#### **Description**

Movie information and user ratings from IMDB.com (long format).

### Usage

```
movies_long
```

#### **Format**

A data frame with 1,579 rows and 8 variables

- title. Title of the movie.
- year. Year of release.
- budget. Total budget (if known) in US dollars
- length. Length in minutes.
- rating. Average IMDB user rating.
- votes. Number of IMDB users who rated this movie.
- mpaa. MPAA rating.
- genre. Different genres of movies (action, animation, comedy, drama, documentary, romance, short).

#### **Details**

Modified dataset from ggplot2movies package.

The internet movie database, <a href="https://imdb.com/">https://imdb.com/</a>, is a website devoted to collecting movie data supplied by studios and fans. It claims to be the biggest movie database on the web and is run by amazon.

Movies were are identical to those selected for inclusion in movies\_wide but this dataset has been constructed such that every movie appears in one and only one genre category.

#### **Source**

https://CRAN.R-project.org/package=ggplot2movies
```

```
dim(movies_long)
head(movies_long)
dplyr::glimpse(movies_long)
```

movies\_wide 21

movies\_wide

Movie information and user ratings from IMDB.com (wide format).

#### **Description**

Movie information and user ratings from IMDB.com (wide format).

#### Usage

movies\_wide

#### **Format**

A data frame with 1,579 rows and 13 variables

- title. Title of the movie.
- year. Year of release.
- budget. Total budget in millions of US dollars
- length. Length in minutes.
- rating. Average IMDB user rating.
- votes. Number of IMDB users who rated this movie.
- mpaa. MPAA rating.
- action, animation, comedy, drama, documentary, romance, short. Binary variables representing if movie was classified as belonging to that genre.
- NumGenre. The number of different genres a film was classified in an integer between one and four.

#### **Details**

Modified dataset from ggplot2movies package.

The internet movie database, <a href="https://imdb.com/">https://imdb.com/</a>, is a website devoted to collecting movie data supplied by studios and fans. It claims to be the biggest movie database on the web and is run by amazon.

Movies were selected for inclusion if they had a known length and had been rated by at least one IMDB user. Small categories such as documentaries and NC-17 movies were removed.

#### **Source**

```

```

```
dim(movies_wide)
head(movies_wide)
dplyr::glimpse(movies_wide)
```

oneway\_anova

One-way analysis of variance (ANOVA)

#### **Description**

Parametric, non-parametric, robust, and Bayesian one-way ANOVA.

#### Usage

```
oneway_anova(
  data,
  Х,
 у,
  subject.id = NULL,
  type = "parametric",
  paired = FALSE,
  digits = 2L,
  conf.level = 0.95,
  effsize.type = "omega",
  var.equal = FALSE,
 bf.prior = 0.707,
  tr = 0.2,
  nboot = 100L,
)
```

### **Arguments**

data

A data frame (or a tibble) from which variables specified are to be taken. Other data types (e.g., matrix,table, array, etc.) will **not** be accepted. Additionally, grouped data frames from {dplyr} should be ungrouped before they are entered as data.

Х

The grouping (or independent) variable from data. In case of a repeated measures or within-subjects design, if subject. id argument is not available or not explicitly specified, the function assumes that the data has already been sorted by such an id by the user and creates an internal identifier. So if your data is **not** sorted, the results *can* be inaccurate when there are more than two levels in x and there are NAs present. The data is expected to be sorted by user in subject-1, subject-2, ..., pattern.

У

The response (or outcome or dependent) variable from data.

subject.id

Relevant in case of a repeated measures or within-subjects design (paired = TRUE, i.e.), it specifies the subject or repeated measures identifier. **Important**: Note that if this argument is NULL (which is the default), the function assumes that the data has already been sorted by such an id by the user and creates an internal identifier. So if your data is not sorted and you leave this argument unspecified, the results can be inaccurate when there are more than two levels in x and there are NAs present.

type A character specifying the type of statistical approach:

• "parametric"

• "nonparametric"

• "robust"

• "bayes"

You can specify just the initial letter.

paired Logical that decides whether the experimental design is repeated measures/within-

subjects or between-subjects. The default is FALSE.

digits Number of digits for rounding or significant figures. May also be "signif" to

return significant figures or "scientific" to return scientific notation. Control the number of digits by adding the value as suffix, e.g. digits = "scientific4" to have scientific notation with 4 decimal places, or digits = "signif5" for 5

significant figures (see also signif()).

conf.level Scalar between 0 and 1 (default: 95% confidence/credible intervals, 0.95). If

NULL, no confidence intervals will be computed.

effsize.type Type of effect size needed for *parametric* tests. The argument can be "eta"

(partial eta-squared) or "omega" (partial omega-squared).

var.equal a logical variable indicating whether to treat the two variances as being equal.

If TRUE then the pooled variance is used to estimate the variance otherwise the Welch (or Satterthwaite) approximation to the degrees of freedom is used.

bf.prior A number between 0.5 and 2 (default 0.707), the prior width to use in calcu-

lating Bayes factors and posterior estimates. In addition to numeric arguments, several named values are also recognized: "medium", "wide", and "ultrawide", corresponding to r scale values of 1/2, sqrt(2)/2, and 1, respectively. In case of

an ANOVA, this value corresponds to scale for fixed effects.

tr Trim level for the mean when carrying out robust tests. In case of an error,

try reducing the value of tr, which is by default set to 0.2. Lowering the value

might help.

nboot Number of bootstrap samples for computing confidence interval for the effect

size (Default: 100L).

... Additional arguments (currently ignored).

#### Value

The returned tibble data frame can contain some or all of the following columns (the exact columns will depend on the statistical test):

- statistic: the numeric value of a statistic
- df: the numeric value of a parameter being modeled (often degrees of freedom for the test)
- df.error and df: relevant only if the statistic in question has two degrees of freedom (e.g. anova)
- p. value: the two-sided p-value associated with the observed statistic
- method: the name of the inferential statistical test
- estimate: estimated value of the effect size

- conf.low: lower bound for the effect size estimate
- conf.high: upper bound for the effect size estimate
- conf.level: width of the confidence interval
- conf.method: method used to compute confidence interval
- conf.distribution: statistical distribution for the effect
- effectsize: the name of the effect size
- n.obs: number of observations
- expression: pre-formatted expression containing statistical details

For examples, see data frame output vignette.

#### One-way ANOVA

The table below provides summary about:

- statistical test carried out for inferential statistics
- type of effect size estimate and a measure of uncertainty for this estimate
- functions used internally to compute these details

#### between-subjects:

### **Hypothesis testing**

Type	No. of groups	Test	Function used
Parametric	> 2	Fisher's or Welch's one-way ANOVA	stats::oneway.test()
Non-parametric	> 2	Kruskal-Wallis one-way ANOVA	stats::kruskal.test()

one\_sample\_test

One-sample tests

### Description

Parametric, non-parametric, robust, and Bayesian one-sample tests.

one\_sample\_test 27

#### Usage

```
one_sample_test(
  data,
  x,
  type = "parametric",
  test.value = 0,
  alternative = "two.sided",
  digits = 2L,
  conf.level = 0.95,
  tr = 0.2,
  bf.prior = 0.707,
  effsize.type = "g",
  ...
)
```

#### **Arguments**

data

A data frame (or a tibble) from which variables specified are to be taken. Other data types (e.g., matrix,table, array, etc.) will **not** be accepted. Additionally, grouped data frames from {dplyr} should be ungrouped before they are entered as data.

Χ

A numeric variable from the data frame data.

type

A character specifying the type of statistical approach:

- "parametric"
- "nonparametric"
- "robust"
- "bayes"

You can specify just the initial letter.

test.value

A number indicating the true value of the mean (Default: 0).

alternative

a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.

digits

Number of digits for rounding or significant figures. May also be "signif" to return significant figures or "scientific" to return scientific notation. Control the number of digits by adding the value as suffix, e.g. digits = "scientific4" to have scientific notation with 4 decimal places, or digits = "signif5" for 5 significant figures (see also signif()).

conf.level

Scalar between 0 and 1 (default: 95% confidence/credible intervals, 0.95). If NULL, no confidence intervals will be computed.

tr

Trim level for the mean when carrying out robust tests. In case of an error, try reducing the value of tr, which is by default set to 0.2. Lowering the value might help.

bf.prior

A number between 0.5 and 2 (default 0.707), the prior width to use in calculating Bayes factors and posterior estimates. In addition to numeric arguments, several named values are also recognized: "medium", "wide", and "ultrawide", corresponding to r scale values of 1/2, sqrt(2)/2, and 1, respectively. In case of an ANOVA, this value corresponds to scale for fixed effects.

28 one\_sample\_test

effsize.type Type of effect size needed for *parametric* tests. The argument can be "d" (for Cohen's d) or "g" (for Hedge's g).

... Currently ignored.

#### Value

The returned tibble data frame can contain some or all of the following columns (the exact columns will depend on the statistical test):

- statistic: the numeric value of a statistic
- df: the numeric value of a parameter being modeled (often degrees of freedom for the test)
- df.error and df: relevant only if the statistic in question has two degrees of freedom (e.g. anova)
- p. value: the two-sided p-value associated with the observed statistic
- method: the name of the inferential statistical test
- estimate: estimated value of the effect size
- conf.low: lower bound for the effect size estimate
- conf. high: upper bound for the effect size estimate
- conf.level: width of the confidence interval
- conf.method: method used to compute confidence interval
- conf. distribution: statistical distribution for the effect
- effectsize: the name of the effect size
- n.obs: number of observations
- expression: pre-formatted expression containing statistical details

For examples, see data frame output vignette.

#### One-sample tests

The table below provides summary about:

- statistical test carried out for inferential statistics
- type of effect size estimate and a measure of uncertainty for this estimate
- functions used internally to compute these details

#### Hypothesis testing

Type	Test	Function used
Parametric	One-sample Student's <i>t</i> -test	stats::t.test()
Non-parametric	One-sample Wilcoxon test	stats::wilcox.test()
Robust	Bootstrap- <i>t</i> method for one-sample test	<pre>WRS2::trimcibt()</pre>
Bayesian	One-sample Student's <i>t</i> -test	<pre>BayesFactor::ttestBF()</pre>

### **Effect size estimation**

pairwise\_comparisons 29

Type Effect size CI available? Function used Parametric Cohen's d, Hedge's g Yes effectsize::cohens\_d(), effectsize::hedges\_g() Non-parametric r (rank-biserial correlation) Yes effectsize::rank\_biserial() trimmed mean Yes WRS2::trimcibt() Robust **Bayes Factor** difference Yes bayestestR::describe\_posterior()

### **Examples**

#### **Description**

Calculate parametric, non-parametric, robust, and Bayes Factor pairwise comparisons between group levels with corrections for multiple testing.

#### Usage

```
pairwise_comparisons(
  data,
  x,
  y,
  subject.id = NULL,
  type = "parametric",
  paired = FALSE,
  var.equal = FALSE,
  tr = 0.2,
  bf.prior = 0.707,
```

```
p.adjust.method = "holm",
digits = 2L,
...
)
```

#### **Arguments**

data

A data frame (or a tibble) from which variables specified are to be taken. Other data types (e.g., matrix,table, array, etc.) will **not** be accepted. Additionally, grouped data frames from {dplyr} should be ungrouped before they are entered as data.

Χ

The grouping (or independent) variable from data. In case of a repeated measures or within-subjects design, if subject.id argument is not available or not explicitly specified, the function assumes that the data has already been sorted by such an id by the user and creates an internal identifier. So if your data is **not** sorted, the results *can* be inaccurate when there are more than two levels in x and there are NAs present. The data is expected to be sorted by user in subject-1,subject-2, ..., pattern.

У

The response (or outcome or dependent) variable from data.

subject.id

Relevant in case of a repeated measures or within-subjects design (paired = TRUE, i.e.), it specifies the subject or repeated measures identifier. **Important**: Note that if this argument is NULL (which is the default), the function assumes that the data has already been sorted by such an id by the user and creates an internal identifier. So if your data is **not** sorted and you leave this argument unspecified, the results *can* be inaccurate when there are more than two levels in x and there are NAs present.

type

A character specifying the type of statistical approach:

- "parametric"
- "nonparametric"
- "robust"
- "bayes"

You can specify just the initial letter.

paired

Logical that decides whether the experimental design is repeated measures/withinsubjects or between-subjects. The default is FALSE.

var.equal

a logical variable indicating whether to treat the two variances as being equal. If TRUE then the pooled variance is used to estimate the variance otherwise the Welch (or Satterthwaite) approximation to the degrees of freedom is used.

tr

Trim level for the mean when carrying out robust tests. In case of an error, try reducing the value of tr, which is by default set to 0.2. Lowering the value might help.

bf.prior

A number between 0.5 and 2 (default 0.707), the prior width to use in calculating Bayes factors and posterior estimates. In addition to numeric arguments, several named values are also recognized: "medium", "wide", and "ultrawide", corresponding to r scale values of 1/2, sqrt(2)/2, and 1, respectively. In case of an ANOVA, this value corresponds to scale for fixed effects.

pairwise\_comparisons 31

p.adjust.method

Adjustment method for p-values for multiple comparisons. Possible methods are: "holm" (default), "hochberg", "hommel", "bonferroni", "BH", "BY", "fdr", "none".

digits

Number of digits for rounding or significant figures. May also be "signif" to return significant figures or "scientific" to return scientific notation. Control the number of digits by adding the value as suffix, e.g. digits = "scientific4" to have scientific notation with 4 decimal places, or digits = "signif5" for 5 significant figures (see also signif()).

... Additional arguments passed to other methods.

#### Value

The returned tibble data frame can contain some or all of the following columns (the exact columns will depend on the statistical test):

- statistic: the numeric value of a statistic
- df: the numeric value of a parameter being modeled (often degrees of freedom for the test)
- df.error and df: relevant only if the statistic in question has two degrees of freedom (e.g. anova)
- p. value: the two-sided p-value associated with the observed statistic
- method: the name of the inferential statistical test
- estimate: estimated value of the effect size
- conf. low: lower bound for the effect size estimate
- conf.high: upper bound for the effect size estimate
- conf.level: width of the confidence interval
- · conf.method: method used to compute confidence interval
- conf.distribution: statistical distribution for the effect
- effectsize: the name of the effect size
- n.obs: number of observations
- expression: pre-formatted expression containing statistical details

For examples, see data frame output vignette.

#### Pairwise comparison tests

```

p\_adjust\_text

p-value adjustment method text

### Description

Preparing text to describe which p-value adjustment method was used

### Usage

```
p_adjust_text(p.adjust.method)
```

### **Arguments**

```
p.adjust.method  
Adjustment method for p-values for multiple comparisons. Possible methods are: "holm" (default), "hochberg", "hommel", "bonferroni", "BH", "BY", "fdr", "none".
```

#### Value

Standardized text description for what method was used.

#### **Examples**

```
p_adjust_text("none")
p_adjust_text("BY")
```

tidy\_model\_expressions

Expressions with statistics for tidy regression data frames

#### **Description**

Expressions with statistics for tidy regression data frames

Currently ignored.

#### Usage

```
tidy_model_expressions(
  data,
  statistic = NULL,
  digits = 2L,
  effsize.type = "omega",
   ...
)
```

#### **Arguments**

data	$A\ tidy\ data\ frame\ from\ regression\ model\ object\ (see\ stats \ Expressions:: tidy\_model\_parameters()).$
statistic	Which statistic is to be displayed (either "t" or "f"or "z" or "chi") in the expression.
digits	Number of digits for rounding or significant figures. May also be "signif" to return significant figures or "scientific" to return scientific notation. Control the number of digits by adding the value as suffix, e.g. digits = "scientific4" to have scientific notation with 4 decimal places, or digits = "signif5" for 5 significant figures (see also signif()).
effsize.type	Type of effect size needed for <i>parametric</i> tests. The argument can be "eta" (partial eta-squared) or "omega" (partial omega-squared).

#### **Details**

When any of the necessary numeric column values (estimate, statistic, p.value) are missing, for these rows, a NULL is returned instead of an expression with empty strings.

#### Note

This is an **experimental** function and may change in the future. Please do not use it yet in your workflow.

#### **Examples**

```
# setup
set.seed(123)
library(statsExpressions)

# extract a tidy data frame
df <- tidy_model_parameters(lm(wt ~ am * cyl, mtcars))

# create a column containing expression; the expression will depend on `statistic`
tidy_model_expressions(df, statistic = "t")
tidy_model_expressions(df, statistic = "z")
tidy_model_expressions(df, statistic = "chi")</pre>
```

tidy\_model\_parameters Convert {parameters} package output to {tidyverse} conventions

### **Description**

Convert {parameters} package output to {tidyverse} conventions

#### Usage

```
tidy_model_parameters(model, ...)
```

#### **Arguments**

model

Statistical Model.

. . .

Arguments passed to or from other methods. Non-documented arguments are digits, p\_digits, ci\_digits and footer\_digits to set the number of digits for the output. If s\_value = TRUE, the p-value will be replaced by the S-value in the output (cf. *Rafi and Greenland 2020*). pd adds an additional column with the *probability of direction* (see bayestestR::p\_direction() for details). groups can be used to group coefficients. It will be passed to the print-method, or can directly be used in print(), see documentation in print.parameters\_model(). Furthermore, see 'Examples' in model\_parameters.default(). For developers, whose interest mainly is to get a "tidy" data frame of model summaries, it is recommended to set pretty\_names = FALSE to speed up computation of the summary table.

#### **Examples**

```
model <- lm(mpg ~ wt + cyl, data = mtcars)
tidy_model_parameters(model)</pre>
```

two\_sample\_test

Two-sample tests

#### **Description**

Parametric, non-parametric, robust, and Bayesian two-sample tests.

#### Usage

```
two_sample_test(
  data,
  Х,
 у,
  subject.id = NULL,
  type = "parametric",
  paired = FALSE,
  alternative = "two.sided",

#### **Arguments**

data

A data frame (or a tibble) from which variables specified are to be taken. Other data types (e.g., matrix,table, array, etc.) will **not** be accepted. Additionally, grouped data frames from {dplyr} should be ungrouped before they are entered as data.

Х

The grouping (or independent) variable from data. In case of a repeated measures or within-subjects design, if subject.id argument is not available or not explicitly specified, the function assumes that the data has already been sorted by such an id by the user and creates an internal identifier. So if your data is **not** sorted, the results *can* be inaccurate when there are more than two levels in x and there are NAs present. The data is expected to be sorted by user in subject-1,subject-2, ..., pattern.

У

The response (or outcome or dependent) variable from data.

subject.id

Relevant in case of a repeated measures or within-subjects design (paired = TRUE, i.e.), it specifies the subject or repeated measures identifier. **Important**: Note that if this argument is NULL (which is the default), the function assumes that the data has already been sorted by such an id by the user and creates an internal identifier. So if your data is **not** sorted and you leave this argument unspecified, the results *can* be inaccurate when there are more than two levels in x and there are NAs present.

type

A character specifying the type of statistical approach:

- "parametric"
- "nonparametric"
- "robust"
- "bayes"

You can specify just the initial letter.

paired

Logical that decides whether the experimental design is repeated measures/withinsubjects or between-subjects. The default is FALSE.

alternative

a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.

digits

Number of digits for rounding or significant figures. May also be "signif" to return significant figures or "scientific" to return scientific notation. Control the number of digits by adding the value as suffix, e.g. digits = "scientific4" to have scientific notation with 4 decimal places, or digits = "signif5" for 5 significant figures (see also signif()).

conf.level

Scalar between 0 and 1 (default: 95% confidence/credible intervals, 0.95). If NULL, no confidence intervals will be computed.

effsize.type

Type of effect size needed for *parametric* tests. The argument can be "d" (for Cohen's d) or "g" (for Hedge's g).

var.equal

a logical variable indicating whether to treat the two variances as being equal. If TRUE then the pooled variance is used to estimate the variance otherwise the Welch (or Satterthwaite) approximation to the degrees of freedom is used.

bf.prior

A number between 0.5 and 2 (default 0.707), the prior width to use in calculating Bayes factors and posterior estimates. In addition to numeric arguments, several named values are also recognized: "medium", "wide", and "ultrawide", corresponding to r scale values of 1/2, sqrt(2)/2, and 1, respectively. In case of an ANOVA, this value corresponds to scale for fixed effects.

tr

Trim level for the mean when carrying out robust tests. In case of an error, try reducing the value of tr, which is by default set to 0.2. Lowering the value might help.

nboot

Number of bootstrap samples for computing confidence interval for the effect size (Default: 100L).

. . .

Currently ignored.

#### Value

The returned tibble data frame can contain some or all of the following columns (the exact columns will depend on the statistical test):

- statistic: the numeric value of a statistic
- df: the numeric value of a parameter being modeled (often degrees of freedom for the test)
- df.error and df: relevant only if the statistic in question has two degrees of freedom (e.g. anova)
- p. value: the two-sided p-value associated with the observed statistic
- method: the name of the inferential statistical test
- estimate: estimated value of the effect size
- conf.low: lower bound for the effect size estimate
- conf. high: upper bound for the effect size estimate
- conf.level: width of the confidence interval
- conf.method: method used to compute confidence interval
- conf.distribution: statistical distribution for the effect
- effectsize: the name of the effect size
- n.obs: number of observations
- expression: pre-formatted expression containing statistical details

For examples, see data frame output vignette.

### Two-sample tests

The table below provides summary about:

- statistical test carried out for inferential statistics
- type of effect size estimate and a measure of uncertainty for this estimate
- functions used internally to compute these details

#### between-subjects:

#### Hypothesis testing

Type	No. of groups	Test	Function used
Parametric	2	Student's or Welch's <i>t</i> -test	stats::t.test()
Non-parametric	2	Mann-Whitney <i>U</i> test	stats::wilcox.test()
Robust	2	Yuen's test for trimmed means	WRS2::yuen()
Bayesian	2	Student's <i>t</i> -test	<pre>BayesFactor::ttestBF()</pre>

#### **Effect size estimation**

Type	No. of groups	Effect size	CI available?	Function used
Parametric	2	Cohen's d, Hedge's g	Yes	effectsize:
Non-parametric	2	r (rank-biserial correlation)	Yes	effectsize:
Robust	2	Algina-Keselman-Penfield robust standardized difference	Yes	WRS2::akp.e
Bayesian	2	difference	Yes	bayestestR:

### within-subjects: Hypothesis testing

Type	No. of groups	Test	Function used
Parametric	2	Student's <i>t</i> -test	stats::t.test()
Non-parametric	2	Wilcoxon signed-rank test	<pre>stats::wilcox.test()</pre>
Robust	2	Yuen's test on trimmed means for dependent samples	WRS2::yuend()

Bayesian 2 Student's t-test BayesFactor::ttestBF()

#### **Effect size estimation**

Type	No. of groups	Effect size	CI available?	Function used
Parametric	2	Cohen's d, Hedge's g	Yes	effectsize:
Non-parametric	2	r (rank-biserial correlation)	Yes	effectsize:
Robust	2	Algina-Keselman-Penfield robust standardized difference	Yes	WRS2::wmcpA
Bayesian	2	difference	Yes	bayestestR:

```
# ----- within-subjects -----
